

# Introduction to Methods

## Part 2: Scope of Variables

Course: CPSC 1150

Instructor: Dr. Bitá Shadgar

Lecture 12

# Learning Outcomes

- Define global and local variables
- Recognize the scope of variables
- Use global variables in methods

# Scope of variables

- Variables don't have meaning everywhere in a program
- A compiler only 'knows' a variable name
  - in the block where it is declared, and
  - after it is declared
- Examples of local variables:
  - A loop counter declared in a for-loop header is local to that for-loop
  - A parameter of a method (or variable declared in a method) is local to that method

## Example

Let's write a program called TestScope to examine the idea of the scope of variables.

# Scope of Local Variables

```
public static void method1() {  
    .  
    .  
    for (int i = 1; i < 10; i++) {  
        .  
        .  
        int j;  
        .  
        .  
        .  
    }  
}
```

The scope of i →

The scope of j →

The diagram uses curly braces to group the code blocks. A vertical line with a horizontal arrow points from the text 'The scope of i' to the opening brace of the 'for' loop. Another vertical line with a horizontal arrow points from the text 'The scope of j' to the opening brace of the loop body. This visually demonstrates that 'i' is in scope for the entire method, while 'j' is only in scope within the loop.

# Scope of Local Variables, cont.

It is fine to declare `i` in two non-nesting blocks

```
public static void method1() {  
    int x = 1;  
    int y = 1;  
    for (int i = 1; i < 10; i++) {  
        x += i;  
    }  
    for (int i = 1; i < 10; i++) {  
        y += i;  
    }  
}
```

It is wrong to declare `i` in two nesting blocks

```
public static void method2() {  
    int i = 1;  
    int sum = 0;  
    for (int i = 1; i < 10; i++) {  
        sum += i;  
    }  
}
```

# Global variables

- Java allows you to use *global variables*.
- They are declared outside all functions and are accessible to all functions in its scope.
- Non-static global variables can not be used in static methods

## Example

```
public class TestScope {  
    static int x = 15;  
    public static void main(String []args){  
        System.out.printf("x is %d ", x);  
    }  
}
```

```
x is 15
```

# Local and Global variables with same name

- If there is a global variable with the same name as local variables in the same scope, local variable has more precedence over the global variable.
- You can use the class name to access the global variable

## Example

```
public class TestScope {  
    static int x = 15;  
    public static void main(String []args){  
        int x = 10;  
        System.out.printf("Local x is %d\n", x);  
        System.out.printf("Global x is %d\n",  
                           TestScope.x);  
    }  
}
```

```
Local x is 10  
Global x is 15
```

# Scope of Global Variables

## Example

```
public class TestScope {  
    static int y = 10;  
    public static void main(String []args){  
        for (int y=0; y<3; ++y){  
            System.out.println(TestScope.y) ;  
            f() ;  
        }  
    }  
    public static void f(){  
        TestScope.y += 10;  
    }  
}
```

```
10  
20  
30
```

# Practice – Letter Grades

- Write a program in Java that given a grade, it prints the correct letter for it. In other words, it prints A for grades between 90 and 100, B for grades 70 or more but less than 90, C for grades 50 or more but less than 70, and F for grades less than 50.

# Practice – Counting Words

- Write a program in Java that gets a text from user input and it counts and prints how many words it has. A word is a sequence of non-WS characters that at least has a letter.
- The following shows examples of the problem:

	input	output
1	<Hello world!>	<Hello world!> has 2 words.
2	<      Hello world!      >	<      Hello world!      > has 2 words.
3	<   Hello      world!   >	<   Hello      world!   > has 2 words.
4	<   Hello      world    !   >	<   Hello      world    !   > has 2 words.
